

MRI Lumbar Spine Report

The MRI of the lumbosacral region demonstrates mild diffuse disc bulges noted at levels L3-L4, L4-L5, S1. There is no significant neural foramina or ligamentum flavum compression. Multilevel left subarachnoid hemorrhage with sequestered blood products are present within the central canal extending from an undetermined cause down toward both cauda equina nerve roots. Associated moderate right side desiccation cyst formation can be seen compressing against the dura mater. A small epidural hematoma appears adjacent to the posterior margin of the L3 vertebral body, likely secondary to trauma associated muscle strain. No evidence of cord compression or myelomass abnormalities detected. Featureless degenerative changes observed throughout the entire spine without any notable pathologic features beyond those described above. Imaging reviewed by Dr. [Physician's Name].
