

MRI Lumbar Spine Report

The lumbar spine X-ray demonstrates mild to moderate spinal canal stenosis and foraminal narrowing between L1-L2, L2-L3, and L3-L4 levels bilaterally, with the stenosis increasing to moderate at the L4-L5 level. Both the L4-L5 and L5-S1 levels also show moderate narrowing. Specifically, the L1-L2, L2-L3, and L3-L4 levels manifest mild changes, whereas the L4-L5 and L5-S1 levels exhibit moderate stenosis and foraminal narrowing.

Additionally, severe subarticular stenosis at the L4-L5 and mild to moderate stenosis at the L3-L4 levels are noted on the left side. The right side shows moderate subarticular stenosis at the L4-L5 and severe changes at the L3-L4 level. Despite these degenerative changes, overall alignment is maintained, and there are no evident fractures, subluxations, or vertebral compression suggesting any acute pathology.

Clinically, these findings are consistent with mild to moderate degenerative changes commonly seen in the lumbar spine in an individual with age-related spondylosis. The presence of moderate subarticular involvement at L4-L5 and L3-L4 may correlate with the patient's symptoms if any discom
