

# MRI Lumbar Spine Report

Okay, here is a concise report focusing solely on degenerative changes, based on the provided MRI images:

## MRI Lumbar Spine Report: Degenerative Classification

### Findings:

**Multilevel Degenerative Disc Disease:** There is evidence of degenerative disc disease affecting multiple levels of the lumbar spine. This includes loss of disc height and signal intensity changes within the intervertebral discs.

**Disc Bulges:** At least one of the discs is exhibiting a mild to moderate bulge, extending beyond the vertebral body margins.

**Facet Arthrosis:** Facet joint hypertrophy and degenerative changes are present, especially in the mid- to lower lumbar spine.

**Ligamentous Degeneration:** There appears to be some thickening of the ligamentum flavum.

### Impression:

Moderate to severe degenerative changes of the lumbar spine are present.

Observed disc bulges and facet arthropathy may contribute to symptomatic axial low back pain.

### Note:

This report specifically focuses on degenerative changes. Additional relevant findings, such as nerve root compression, or soft tissue pathology are not detailed here.

This is a simplified assessment, a full report should be done by a licensed Radiologist.
