

MRI Lumbar Spine Report

The patient presents with moderate right subarachnoid space narrowing secondary to disc protrusion of the L4-L5 levels. A mild left side feature is noted, involving both facet joints (both sides). No significant neural foramina or exit stenosis are identified. Featureless lumbosacral ligamentous hypertrophy has been observed. Diffuse bony sclerosis marginally abuts by paraspinal muscles; no evidence for ossification within the annulus fibrosus or endplate changes were seen. Cervical canal remains adequately wide without compression features. Multilevel degenerative changes have occurred throughout the lower cervical spine, including modest central and lateral recessive nerve root canals associated with dorsolateral bulging disc material along all motion segments from N6 downward. Mild diffuse desiccation cyst formation may be present due to chronicity. This finding does not appear to compress any
