

MRI Lumbar Spine Report

The lumbar spine demonstrates mild spinal canal stenosis at the L1-L2, L2-L3, L3-L4, L4-L5, and L5-S1 levels, consistent with mild intervertebral narrowing, which may suggest early degenerative changes. Additionally, there is moderated right-sided neural foraminal stenosis noted at the L4-L5 and L5-S1 levels, which may indicate some facet osteophytes impinging on the spinal nerve canal.

Despite these findings, there is also mild-to-moderate, primarily left-sided facet degeneration observed. The left intervertebral foraminal spaces are constricted at the L4-L5, and moderate degeneration is present, which could potentially contribute to nerve root compression. The subarticular spaces of the lumbar vertebrae, including the L1-L2, L2-L3, L3-L4, L4-L5, and L5-S1 levels, are within normal limits, although moderate degeneration is noted at the L4-L5 and L5-S1 with mild to minimal changes.

Overall, the patient appears to have mild degenerative changes without significant clinical significance. It is recommended that the patient undergo periodic radiographic evaluations to monitor any progression of degenerative changes and manage symptoms accordingly.
