

MRI Lumbar Spine Report

The MRI of the lumbar spine shows mild diffuse disc bulges with annular tears noted. There is no evidence of significant central or lateral recess stenosis. Multilevel left subarachnoid hemorrhage (SAH) is present likely secondary to an undiagnosed vascular anomaly such as arterial malformation or dural avulsion glioma. No other pathological changes are identified within the lumbosacral region. A follow-up study may be warranted for further evaluation. Clinically stable features without neurological deficits reported by patient. Recommendation for close monitoring due to complex imaging appearance including multifocal SAH. Please correlate these findings carefully before any treatment decisions are made. Patient should also undergo appropriate medical work up prior to surgery if indicated. Imaging reviewed by Dr. [Physician's Name]. Radiologist signature dated MMXXIII
