

MRI Lumbar Spine Report

The patient's MRI of the lumbosacral region shows mild diffuse disc bulges with no significant neural foraminal or central canal compression. Multilevel left-side subarachnoid hemorrhage is noted, likely secondary to an undiagnosed cerebrovascular anomaly such as dural arteriovenous fistula (DAVF). No evidence of cord compression. A follow-up study including digital angiography may be indicated for further evaluation. Clinically correlated with neurology consultation recommended due to associated symptoms. Please note this finding requires careful interpretation by neuroradiologists experienced in vascular imaging studies. An abnormal signal intensity within the right ventricle has been observed which does not correlate well with any known pathology seen elsewhere; it could represent benign age changes but warrants close observation if asymptomatic. Imaging reviewed by Dr. [Name].
