

MRI Lumbar Spine Report

The MRI of the cervical and thoracic spine demonstrates diffuse multilevel central canal narrowing with moderately severe right-side cauda sacrum compression. A large left lateral recess meningeal cyst is noted compressing both exit foramina as well as encroaching upon the descending lumbosacral nerve roots (L3–S1). Diffused disc bulges are seen between L2 – S1 levels mimicking ligamentum flavum hypertrophy. Left subarachnoid hemorrhage is present without evidence of aneurysm or trauma. Feature 1 [Note]: Multilevel degenerative changes involving facet joints associated with annular tears. Grade I desiccation features have been observed within multiple intervertebral spaces. No significant neural elements compression has been identified apart from feature #6 described below. Descriptive notes for notable lesions
