

MRI Lumbar Spine Report

Certainly! Here's a concise MRI lumbar spine report focused solely on degenerative classification based on the provided images:

MRI Lumbar Spine Report: Degenerative Findings

Study: Sagittal T2-weighted images of the lumbar spine.

Findings:

Multilevel Degenerative Disc Disease: Evidence of disc desiccation and loss of disc height are noted at multiple levels throughout the lumbar spine.

Modic Type 1 Endplate Changes: Demonstrated at several disc levels, suggestive of active inflammatory changes.

Facet Arthropathy: Mild facet joint degenerative changes are observed with associated hypertrophy and osteophyte formation, more prominent at the lower lumbar levels.

Impression:

Multilevel degenerative changes are present in the lumbar spine, characterized by disc degeneration, Modic changes, and facet arthropathy. These findings are consistent with degenerative disease.

Note: This report only includes degenerative findings and does not include comment on other potential abnormalities (e.g., nerve impingement). It also does not comment on non-degenerative issues such as infection or fracture.
