

MRI Lumbar Spine Report

Certainly, here's a concise report focusing solely on degenerative changes observed in the lumbar spine MRI images:

MRI Lumbar Spine Report

Findings:

Intervertebral Discs: Multilevel degenerative disc disease is present, characterized by loss of disc height, desiccation (decreased signal intensity), and presence of annular bulging.

Vertebral Endplates: Mild to moderate Modic type 1 changes are visible at several levels.

Facet Joints: Facet arthropathy is demonstrated at the lower lumbar levels.

Spinal Canal and Neural Foramen: There is mild narrowing of the spinal canal and neural foramen due to the combination of disc bulging and facet arthropathy.

Degenerative Classification:

Mild to moderate degenerative changes are seen at multiple levels in the lumbar spine. The changes are primarily located at the intervertebral discs, facet joints, and vertebral endplates. This includes intervertebral disc disease, facet arthropathy, and Modic changes. There is some mild stenosis of the neural foramen.
